How do programs communicate?

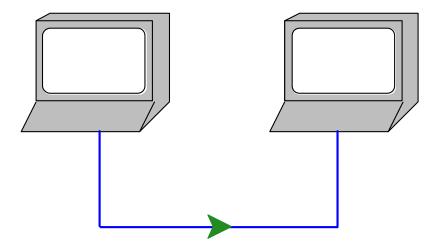

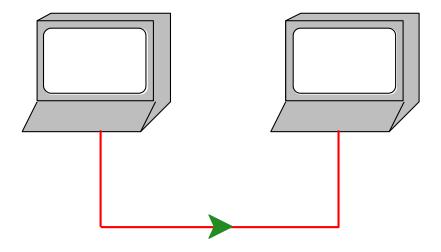

How do programs communicate? Files...

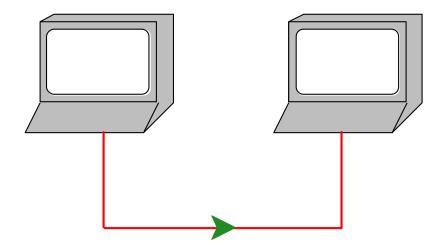

How do programs communicate? Files... Network...

How do programs communicate? Files... Network... Stdin...

How do programs communicate? Files... Network... Stdin... Etc.

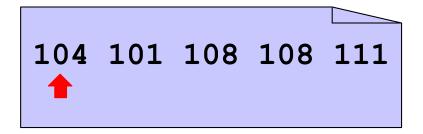

But what's in a file or sent over the network?

Operating systems provide files, network connections, etc. as **byte stream** objects

A byte is a number between 0 and 255

A **stream** is a sequence with a counter and an operation: **read-byte** or **write-byte**

(read-byte in)

Operating systems provide files, network connections, etc. as **byte stream** objects

A byte is a number between 0 and 255

A **stream** is a sequence with a counter and an operation: **read-byte** or **write-byte**

(read-byte in) $\rightarrow 104$

Operating systems provide files, network connections, etc. as **byte stream** objects

A byte is a number between 0 and 255

A **stream** is a sequence with a counter and an operation: **read-byte** or **write-byte**

```
(read-byte in) \rightarrow 104 (read-byte in) \rightarrow 101
```

Operating systems provide files, network connections, etc. as **byte stream** objects

A byte is a number between 0 and 255

A **stream** is a sequence with a counter and an operation: **read-byte** or **write-byte**

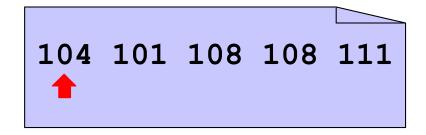

```
104 101 108 108 111
```

```
(read-byte in) \rightarrow 104 (read-byte in) \rightarrow 108 (read-byte in) \rightarrow 101 (read-byte in) \rightarrow 111 (read-byte in) \rightarrow 108 (read-byte in) \rightarrow eof
```

Operating systems provide files, network connections, etc. as **byte stream** objects

A byte is a number between 0 and 255

A **stream** is a sequence with a counter and an operation: **read-byte** or **write-byte**

fgetc(in)

Operating systems provide files, network connections, etc. as **byte stream** objects

A byte is a number between 0 and 255

A **stream** is a sequence with a counter and an operation: **read-byte** or **write-byte**

 $\texttt{fgetc(in)} \rightarrow \texttt{104}$

Operating systems provide files, network connections, etc. as **byte stream** objects

A byte is a number between 0 and 255

A **stream** is a sequence with a counter and an operation: **read-byte** or **write-byte**

$$\texttt{fgetc(in)} \rightarrow \texttt{104}$$

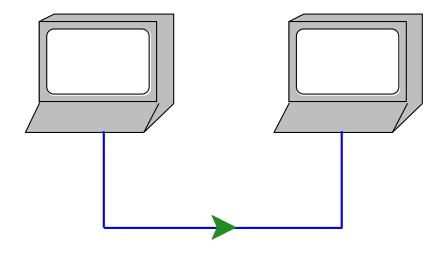

$$\texttt{fgetc(in)} \rightarrow \texttt{101}$$

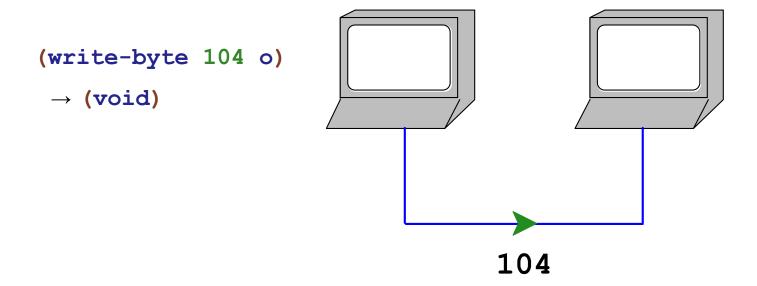

Operating systems provide files, network connections, etc. as **byte stream** objects

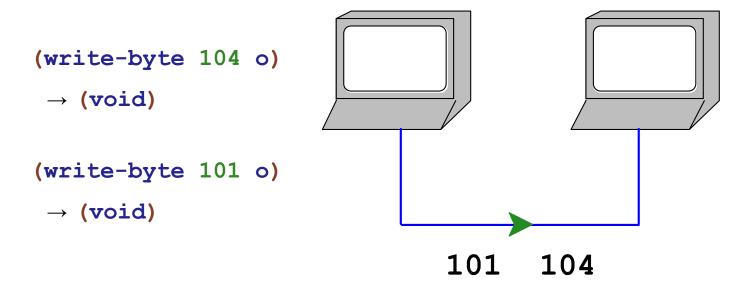

A byte is a number between 0 and 255

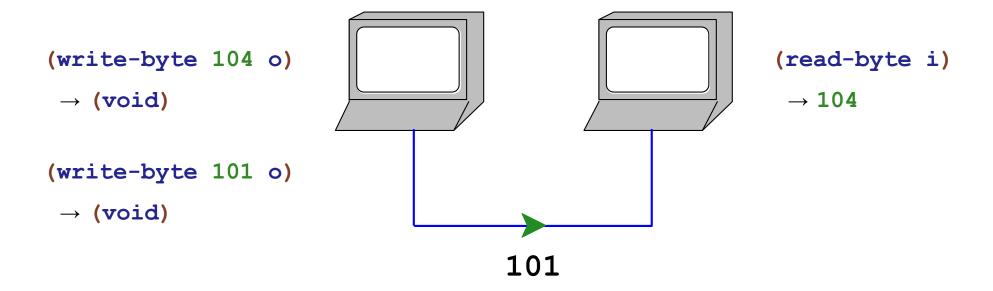

A **stream** is a sequence with a counter and an operation: **read-byte** or **write-byte**

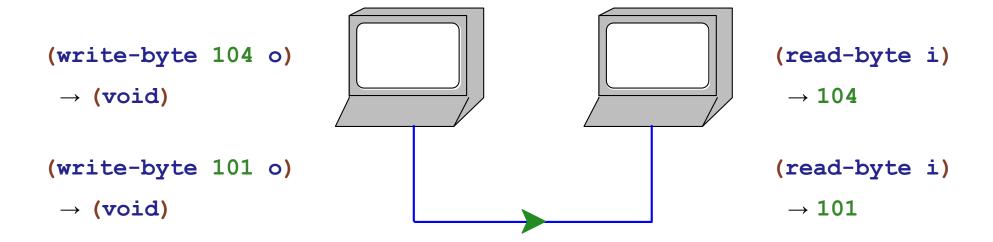

```
\begin{array}{ll} \text{fgetc (in)} \rightarrow 104 & \text{fgetc (in)} \rightarrow 108 \\ \text{fgetc (in)} \rightarrow 101 & \text{fgetc (in)} \rightarrow 111 \\ \text{fgetc (in)} \rightarrow 108 & \text{fgetc (in)} \rightarrow -1 \\ \end{array}
```

Encoding

To communicate information other than small numbers, it must be **encoded**

To encode English text, map each *character* to a byte

```
#\a ⇒ 97
#\b ⇒ 98
#\c ⇒ 99
...
#\A ⇒ 65
...
#\( ⇒ 40
#\) ⇒ 41
#\1 ⇒ 48
```

19

This character encoding is so popular that byte streams are sometimes viewed as **character streams**

```
#\h #\e #\l #\l #\o
```

(read-char in)

This character encoding is so popular that byte streams are sometimes viewed as **character streams**

(read-char in) → #\h

This character encoding is so popular that byte streams are sometimes viewed as **character streams**

```
(read-char in) → #\h
```

(read-char in) → #\e

This character encoding is so popular that byte streams are sometimes viewed as **character streams**

```
(read-char in) \rightarrow \#\h
(read-char in) \rightarrow \#\e
...
(read-char in) \rightarrow eof
```

This character encoding is so popular that byte streams are sometimes viewed as **character streams**

fgetc(in)

This character encoding is so popular that byte streams are sometimes viewed as **character streams**

fgetc(in)
$$\rightarrow$$
 'h' /* = 104 */

This character encoding is so popular that byte streams are sometimes viewed as **character streams**

fgetc(in)
$$\rightarrow$$
 'h' /* = 104 */
fgetc(in) \rightarrow 'e' /* = 101 */

This character encoding is so popular that byte streams are sometimes viewed as **character streams**

fgetc(in)
$$\rightarrow$$
 'h' /* = 104 */
fgetc(in) \rightarrow 'e' /* = 101 */

•••

fgetc(in)
$$\rightarrow$$
 -1

Accessing Streams

Stream types:

- Racket:
 - o input port
 - output port
- Java:
 - InputStream
 - PrintStream
- C:
 - FILE*

Accessing Streams

Getting standard input, output, and error-output:

```
• Racket:
```

```
o (current-input-port)
```

- o (current-output-port)
- o (current-error-port)

• Java:

- System.out
- System.in
- System.err
- C with #include <stdio.h>:
 - o stdin
 - o stdout
 - o stderr

Accessing Streams

Reading or writing a file:

```
Racket:
```

```
(open-input-file filename)(open-output-file filename)
```

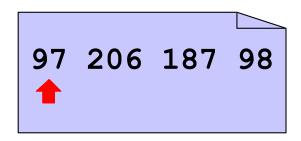

• Java:

- new BufferedReader (new FileReader (filename))
- o new BufferedWriter(new FileWriter(filename))
- C with #include <stdio.h>:
 - o fopen (filename, "rb")
 - fopen (filename, "wb")

Character Streams in Racket

```
(define o (open-output-file "ex1"))
(write-char #\h o)
(write-char #\e o)
(close-output-port o)
(define i (open-input-file "ex1"))
(check-expect (read-char i) #\h)
(check-expect (read-char i) #\e)
(close-input-port i)
```

Note: Racket term for **stream** is **port**

97 206 187 98

(read-char in)
$$\rightarrow \#\a$$

(read-char in) $\rightarrow \#\\lambda$

(read-char in) $\rightarrow \#\b$

Encoding: Characters in C

In C, char just means "byte"

In C, char just means "byte"

fgetc(in) - 'a'

In C, char just means "byte"

fgetc(in) - 'a'

fgetc(in) \rightarrow 'Î'

In C, char just means "byte"

In C, char just means "byte"

97 206 187 98

fgetc(in)
$$\rightarrow$$
 'a'

fgetc(in) \rightarrow 'Î'

fgetc(in) \rightarrow ' \rightarrow '

fgetc(in) \rightarrow 'b'

Some Character Encoding Standards

- ASCII
 - "Characters" 0 to 127
 - A kind of English plus computer creole
- Latin-I
 - "Characters" 0 to 255
 - A kind of Western Europe plus computer creole
 - A superset of ASCII
- UTF-8
 - "Characters" 0 to 917999 or so
 - Roughly covers all languages on Earth
 - A superset of ASCII
- UTF-16
 - Same coverage as UTF-8
 - Uses 2 or 4 bytes for each character

• ...

Communicating Strings

One string: encode as a sequence of characters

Multiple strings: need a way to mark the end of one string

The most popular encoding is *line-based*:

- Use a newline (encoded as 10) to separate strings
 - o #\newline or '\n'
- Works for strings that don't contain newlines
- Racket:
 - o (read-line input-port)
- C:
 - fgets (buffer, len, stream)

CRLF versus LF

Sometimes, lines are separated by two characters (CRLF: 13 then 10) instead of one (LF: 10):

```
"one\ntwo\n" versus "one\r\ntwo\r\n"
```

The encoding convention depends on the platform

Opening a file in "text mode" reads CRLF or LF as newline, as appropriate for a given platform

Racket:

```
(open-input-file #:mode 'text filename)(open-output-file #:mode 'text filename)
```

• C:

```
o fopen (filename, "r")
```

o fopen (filename, "w")

Communicating More Than Characters

To read and write aquariums, we need to communicate lists of (large) numbers

Again, we must encode:

Number List Serialization

```
A <numlist> is either
   #\.
   <num> #\space <numlist>
A <num> is either
   <digit>
   <num> <digit>
A <digit> is either
   #\0
   #\1
   #\9
```

Number List Writer

```
; write-numlist : list-of-num output-port -> void
(define (write-numlist 1 p)
  (cond
   [(empty? 1) (write-char #\. p)]
   [else (begin
           (write-num (first 1) p)
           (write-char #\space p)
           (write-numlist (rest 1) p))]))
; write-num : num output-port -> void
(define (write-num n p)
  (cond
   [(< n 10) (write-digit n p)]</pre>
   [else (begin
           (write-num (quotient n 10) p)
           (write-digit (remainder n 10) p))]))
; write-digit : num [0-9] output-port -> void
(define (write-digit n p)
  (cond
   [(= n 0) (write-char #\0 p)]
   . . .
   [(= n 9) (write-char #\9 p)]))
```

Number List Parsing

Parse using an equivalent but more convenient form:

```
A <numlist> is either
                                            A <numlist> is either
   #\.
                                                #\.
   <num> #\space <numlist>
                                                #\0 <num> <numlist>
A <num> is either
                                                #\9 <num> <numlist>
   <digit>
   <num> <digit>
                                            A <num> is either
                                                #\space
A <digit> is either
                                                #\0 <num>
   #\0
   #\1
                                                #\9 < num>
   #\9
```

Number List Reader

```
; read-numlist : input-port -> list-of-num
(define (read-numlist p)
  (local [(define c (read-char p))]
    (cond
     [(char=? #\. c) empty]
     [(char-digit? c) (cons (read-number p (digit-val c))
                             (read-numlist p))])))
; read-number : input-port num -> num
(define (read-number p n)
  (local [(define c (read-char p))]
    (cond
     [(char=? #\space c) n]
     [(char-digit? c)
      (read-number p (+ (* n 10) (digit-val c)))])))
; char-digit? : char -> bool
. . .
; digit-val : char -> num
. . .
```

I/O Libraries

You don't always have to start from scratch

```
• Racket:
```

```
• read and write
```

• read-line and displayln

• read-xml and write-xml

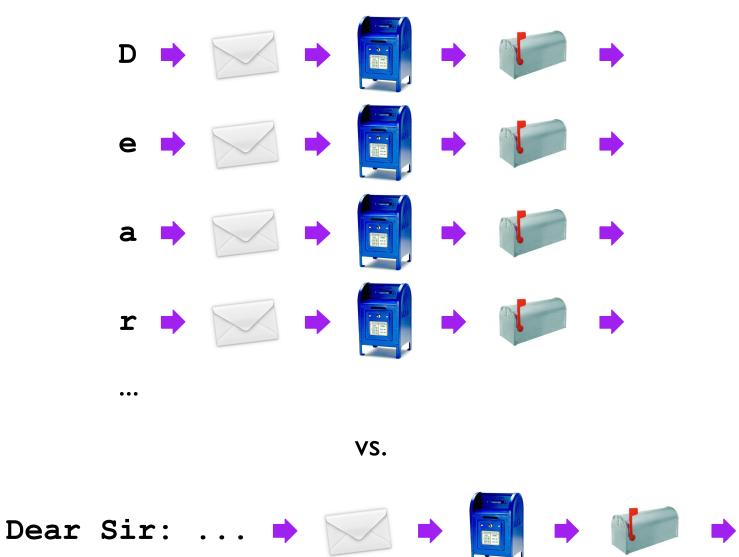

O ...

• C:

• fscanf and fprintf

O ...

Buffers

Buffers

A **buffer** is why you see no output from int main() { printf("hello"); crash(); **Line-buffering** is why you do see output from int main() { printf("hello\n"); crash();

... unless you redirect to an output file

Buffers

Flushing buffers:

- Racket:
 - o (flush-output output-port)
- C:
 - o fflush (stream)
