ALGORITHM ANALYSIS

cs2420 | Introduction to Algorithms and Data Structures | Spring 2016
administrivia...
-assignment 2 is due Thursday at midnight

-clicker participation from Thursday is on Canvas
last time...
generics
-we always see <> associated with ArrayList...

ArrayList<Shape> list = new ArrayList<Shape>();

-ArrayList is a generic class — we can create any version of it that we want

-generic programming: algorithms are written in terms of types to-be-specified-later
  -algorithms instantiated when needed for specific types defined by parameters
-here’s what the code actually looks like:

```java
public class ArrayList<T> {
    T storage[];
    int capacity, numItems;

    public void add(T item)
    { ... }
}

-the placeholder T is replaced with the real type when you instantiate an ArrayList with <>

-T can be used as a type anywhere in ArrayList class
-generics allow for type-checking at compile time instead of run-time

-can detect type mismatch BEFORE your code runs
BEFORE GENERICs:

ArrayList l;
l.add(new String(“hi”));
Shape i = (Shape)l.get(0); // crash

ALTERNATIVE:

ArrayList<String> l;
l.add(new String(“hi”));
Shape i = (Shape)l.get(0); // compile error

COMPILE-TIME ERRORS ARE ALWAYS BETTER THAN RUN-TIME!
-static methods can have their own generic types

-declare the generic type before the return type:
public static <T> boolean doWork(…){…}

-we can refer to T as a type within that method only!

-example:
public static <T> boolean contains(T[] array, T item) {
    for(int i=0; i < array.length; i++)
        if(array[i].equals(item))
            return true;

    return false;
}
today...
-algorithm analysis
-complexity growth rate
-big-O notation
algorithm analysis
- correctness is only half the battle

- programs are expected to terminate in a reasonable amount of time

- running time of a program is strongly correlated to the choice of algorithms used in problem solving

- how much time and space does an algorithm require?
example...
finding a word in a dictionary

ALGORITHM 1:

1) start on the first page, first entry

2) if word not found, move to the next entry

3) if very end of dictionary reached, word not found

IS THIS ALGORITHM CORRECT?

1) yes  
2) no

CAN WE DO BETTER?

1) yes  
2) no

channel: 41
session: 2016cs2420
finding a word in a dictionary

ALGORITHM 2:

1) guess which page the entry is on

2) did we go too far?
   - go back some pages

3) did we not go far enough?
   - go forward some pages

4) continue narrowing

WHAT DOES THIS ALGORITHM ASSUME ABOUT THE DICTIONARY?
- **Algorithm 1: Linear Search**
  - Running time directly related to size of dictionary
  - Assume 180K words, and 0.25s to check one word
  - 12 hours to complete!

- **Algorithm 2: Binary Search**
  - More like what humans do
  - 4 seconds to complete!

- What if the dictionary doubles?

**Algorithm 1 Run-Time?**

1) time * 0.5  
2) time * 2  
3) time + 0.25  
4) time + 10

**Algorithm 2 Run-Time?**

1) time * 0.5  
2) time * 2  
3) time + 0.25  
4) time + 10

TIME \* 2 \(\rightarrow\) \(O(N)\)  
TIME + 0.25 \(\rightarrow\) \(O(\log N)\)
- A **logarithm** is an exponent indicating the power to which a base is raised to produce a given number.

\[ \log_b N = X \quad B^X = N \]

**How many bits does it take to represent a number?**

- By default the base is 2 … we’ll come back to this.

- The logarithm grows slowly:
  
  \[ 9 < \log 1000 < 10 \]
  \[ 19 < \log 1,000,000 < 20 \]
  \[ 29 < \log 1,000,000,000 < 30 \]

- \( N \log N \) is closer to \( N \) than \( N^2 \).
why is binary search \( O(\log N) \)?

why is the default base 2?
finding a word in a dictionary

- binary search will **always** win for large dictionaries
  - as \( N \) increases, the gap between the algorithms becomes larger

- linear search has linear growth rate
  - graph is a ______ line
  - run time for \( N = T \) units of time
  - run time for \( 2N = 2T \) units of time

- binary search has logarithmic growth rate
  - run time for \( N = T \) units of time
  - run time for \( 2N = T + \_ \) units of time

1) exponential
2) straight
3) negative-slope

1) 1
2) 2
3) 10
growth rate
typical run-time complexities

![Graph showing typical run-time complexities]

- $N^2$ and $N^3$ are typically not acceptable for moderate input sizes!

**Typical run-time complexities:**

- $\log(N)$
- $N$
- $N \log N$
- $N^2$
- $N^3$
- knowing that $F(N) < G(N)$ for a particular $N$ is not very useful

- instead, we measure the functions’ growth rates

- for sufficiently large $N$, a function’s growth rate is determined by its dominate term

$10N^2 + 40N + 760 \rightarrow$ WHAT IS THE DOMINATE TERM?

| $c$ | constant |
| $\log N$ | logarithmic |
| $N$ | linear |
| $N \log N$ | linearithmic |
| $N^2$ | quadratic |
| $N^3$ | cubic |

increasing growth rate
how to get log growth?

- how many bits are needed to represent $N$ consecutive integers?

- starting at $x=1$, how many iterations of $x \times 2$ before $x \geq N$?
  - the repeated doubling principle

- starting at $x=N$, how many iterations of $x/2$ before $x \leq 1$?
  - the repeated halving principle
big-O notation
-big-O notation \( O \) is used to capture the dominate term in an algorithm
  -assuming large \( N \)!

-for example, the running time of a quadratic algorithm is \( N^2 \) is specified \( O(N^2) \)
  -read “order N squared”

-this notation allows us to establish a relative order among algorithms
  -\( O(N \log N) \) is better than \( O(N^2) \)
what’s code got to do, got to do with it…

- $O(N^2)$ and $O(N^3)$ are impractical for most $N$

-clever programming tricks CANNOT make an inefficient algorithm fast
  - a poorly coded linear algorithm trumps a quadratic algorithm in a highly efficient machine language

**TAKE AWAY:**

OPTIMIZING THE ALGORITHM (OR CHOOSING THE BEST ONE) WILL GET YOU MUCH FURTHER THAN OPTIMIZING THE CODE
worst, average, best

-worst-case is a guarantee on all inputs — it will never be worse than this

-average-case is the common case, measured over all possible inputs
  -this is the most useful!

-best-case is the absolute fastest that an algorithm can terminate
  -we don’t care about this because it rarely happens
example...
finding the maximum item in an array

Algorithm?

1) initialize \( \text{max} \) to the first element

2) scan through each item in the array
   - if the item is greater than \( \text{max} \), update \( \text{max} \)

What is the big-O complexity of this algorithm?

1) \( c \)
2) \( \log N \)
3) \( N \)
4) \( N \log N \)
5) \( N^2 \)
6) \( N^3 \)
finding the smallest difference

ALGORITHM?

```java
diff = MAX_INTEGER;
for(int i=0; i<array.length-1; i++)
{
    num1 = array[i];
    for(int j=i+1; j<array.length; j++)
    {
        num2 = array[j];
        if (abs(num1-num2) < diff)
            diff = abs(num1-num2);
    }
}
return diff;
```

WHAT IS THE BIG-O COMPLEXITY OF THIS ALGORITHM?

1) c  
2) log N  
3) N  
4) N log N  
5) N^2  
6) N^3
analyze the running time

for(int i=0; i<n; i+=2)
    sum++;

for(int i=0; i<n; i++)
    for(int j=0; j<n*n; j++)
        sum++;

for(int i=0; i<n; i*=2)
    sum++;
