UNIVERSITY OF UTAH
ELECTRICAL & COMPUTER ENGINEERING DEPARTMENT

ANTENNA THEORY AND DESIGN

ECE 5324/6234

FINAL EXAMINATION

April 30, 2009

For students taking a two-hour final examination, do all four problems
(maximum score = 110 points)

For students taking a one-hour final examination, do Problems 1, 2, and 3
(maximum score = 80 points)
1. (30 points)

10 a. Calculate the gain in dBi in the axial direction ($\phi = 0$) for a half-wave dipole that is placed axially at a distance of $0.3\lambda$ from the corner of a 90° corner reflector antenna at a frequency of 400 MHz. For this antenna, assume a feed point impedance $Z_I = 47 + j100\Omega$.

You may be able to compare the gain that you get with the gain for this antenna given on page 57 of the Class Notes (which unfortunately is in dBi rather than dBi).

**Hints:** Use Eq. 5-48 of the Text to obtain max value of AF. Note that for an antenna system (from pp. 32, 33 fo Class Notes)

\[
\text{Gain}_{\text{dBi}} = 10 \log \left( \frac{R_{A0}}{R_{Ai}} \frac{|AF|_{\text{max}}^2}{1} \right)
\]

Convert the gain in dBi to dBd.

5 b. Calculate the effective $A_e$ if this antenna were used as a receiving antenna.

5 c. Calculate the length of the dipole and the distances of the antenna from the corner of the 90° corner reflector.

10 d. Design an inverted-L matching circuit of the following configuration to conjugate-match this antenna to a source of impedance $Z_s = 100 + j75\Omega$

![Inverted-L Matching Circuit Diagram](image)

Note that for conjugate matching, we need $Z_{AB} = Z_{s*} = 100 - j75\Omega$.

Calculate the values of the reactances $jX_{se}$ and $jX_{sh}$.
1. \( Z_i = 47 + j100 \Omega \)

Thus \( R_i = 47 \Omega \)

For a \( 9^\circ \) corner reflector antenna, from Eq. 5.48

\[
AF(\theta = 9^\circ, \Phi = 0) = 2 \cos\left(\beta s \cos \Phi \right) \left| \frac{-2 \cos(\beta s \sin \Phi)}{\Phi = 0} \right|
\]

\[
= 2 \cos(\beta s) - 2 = -2.618
\]

Since \( \beta s = \frac{2\pi}{\lambda} \times 0.3 \lambda = 0.6 \pi \), \( \cos(0.6 \pi) = -0.309 \)

Gain \( G_{dB} = 10 \log \left( \frac{7.3^2 \times (2.618)^2}{47} \right) = 10 \log(10.645) = 10.27 \text{ dBi} \)

This may be compared to a gain of approximately 10.1 - 10.2 dBi from the graph on p. 57 of Class Notes. The slight difference in the calculated gain is due to the difficulty in impedance \( Z_i \) from the graphs for real and imaginary parts of the impedance \( Z_i \) from p. 58 of the Class Notes.

Gain in dBi = 10.27 + gain of half-wave dipole = 10.27 + 2.15 = 12.42 dBi

(see p. 6 of Class Notes)

b. \( \frac{4\pi A_e}{\lambda^2} = \frac{12.42}{10^2} = 0.1242 = 1.64 \times 10.645 = 17.46 \)

\[ A_e = \frac{(75)^2}{4\pi} \times 17.46 = 0.782 \text{ m}^2 \]

c. Length of the dipole = \( 0.5 \lambda = \frac{7.5}{2} = 37.5 \text{ cm} \)

Spacing \( S \) to the corner of the \( 9^\circ \) reflector = \( 0.3 \lambda = 22.5 \text{ cm} \)
Using a procedure similar to that on p. 56 of Class Notes

\[ Y_{AB} = \frac{1}{100 - j75} = \frac{100 + j75}{(100)^2 + (75)^2} = \frac{1}{47 + j(X_{se} + 100)} \]  \hspace{1cm} (1)

Equating real and imaginary parts of the equation on both sides of Eq. (1), we can write

\[ \frac{47}{(47)^2 + (X_{se} + 100)^2} = \frac{100}{15625} = \frac{1}{156.25} \]  \hspace{1cm} (2)

\[ 47 \times 156.25 = (47)^2 + (X_{se} + 100)^2 \]  \hspace{1cm} (3)

\[ X_{se} + 100 = \pm \sqrt{47 \times 109.25} = \pm 71.66 \]  \hspace{1cm} (4)

\[ X_{se} = \boxed{-28.34}, \quad -71.66 \]  \hspace{1cm} (5)

We take the smaller value of \( X_{se} \) (because it will vary less as frequency changes)

\[ X_{se} = -28.34 \]

Equating the imaginary parts on both sides of Eq. (1), we can write

\[ \frac{-j \times 71.66}{(47)^2 + (X_{se} + 100)^2} = \frac{-j}{47 \times 156.25} \times X_{sh} \]

from Eq. (3)

\[ X_{sh} = \frac{47 \times 156.25}{71.66} = 102.48 \ \Omega \]
2. (20 points)

A helical antenna to be used as a radiator at 1.65 GHz has the following specifications:

Diameter of the helix = 2.25"
Number of turns = 10
Spacing S (pitch) = 0.8"

pts
4 a. For this antenna, calculate $C/\lambda$.

For the axial mode of radiation, which is typical for this antenna, calculate:

4 b. gain in decibels.
4 c. input resistance.
4 d. half-power beam width in degrees.
4 e. axial ratio for the radiated fields.
2. The material on the axial mode of a helical antenna \((\frac{3}{4} < C/\lambda < \frac{4}{3})\) is discussed on pp. 235–239 of the Spatman and Thiele Text.

a. For this antenna, \(\frac{C}{\lambda} = \frac{\pi D}{\lambda} = \frac{\pi \times 2.25 \times 2.54}{30 / 1.65} = 0.987\).

Note that \(\lambda = 30 / 1.65 = 18.18\) cm.

b. From Eq. 6.34 on p. 237 of the Text,
\[
G = 6.2 \left(\frac{C}{\lambda}\right)^2 \frac{N S}{\lambda} = 6.2 \times (0.987)^2 \times \frac{10 \times 0.8 \times 2.54}{18.18} \approx 6.75\, \text{dB}
\]

c. Input resistance from Eq. 6.36 on p. 238 of the Text,
\[
R_A = 140 \times \frac{C}{\lambda} = 140 \times 0.987 \approx 138.2 \, \Omega
\]

d. HPBW from Eq. 6.33 of the Text,
\[
HP = \frac{65^\circ}{0.987 \sqrt{\frac{10 \times 0.8 \times 2.54}{18.18}}} \approx 62.29^\circ
\]

e. From Eq. 6.35 of the Text,
\[
\text{Axial Ratio} = |AR| = \frac{2N+1}{2N} = \frac{21}{20} = 1.05
\]
3. (30 points)

Design a parabolic antenna with a gain of 40 dBi at 12.5 GHz. For this antenna, assume \( n = 2 \) parabolic taper on a pedestal with edge illumination that is -14 dB relative to the illumination at the center. In particular, calculate the following:

<table>

</tbody>
</table>
3. a. From p. 320 of the Text (Table 7-1 part b) for \( n = 2 \) parabolic taper on a pedestal for edge illumination of \(-14\text{ dB}\) relative to the illumination at the center

\[ E_t = 0.792 \]

\[ \text{Gain} = 0.792 \left( \frac{\pi D^2}{\lambda} \right) = 10^4 \text{ (40 dB\text{i})} \]

\[ \lambda = \frac{30}{12.5} = 2.4\text{ cm} \]

\[ D = \sqrt{\frac{10^4}{0.792}} \times \frac{2.4}{\pi} = 85.84\text{ cm} \]

b. \( HP = 1.23 \frac{\lambda}{D} \text{ rad} = 1.9^\circ \)

c. \[ \frac{4\pi A_e}{\lambda^2} = \text{Gain} = 10^4 \]

\[ A_e = 0.792 \frac{\pi D^2}{4} = 0.792 \text{ A}_{\text{physical}} = 4583.5\text{ cm}^2 \]

or \[ 0.4583\text{ m}^2 \]

d. Side lobe level = \(-31.7\text{ dB}\) relative to the major lobe

f. From Eq. 2-99 on p. 80 of the Text

\[ P_r (\text{dBm}) = P_t (\text{dBm}) + G_t (\text{dB}) + G_r (\text{dB}) - 20 \log \frac{\Omega}{R (\text{km})} - 20 \log f_{\text{MHz}} - 32.44 - \text{loss of the atmosphere in dB} \]

\[ = 50 + 40 + 35 - 20 \log \left( \frac{35.600}{91.03} \right) - 32.44 - 2 \]

\[ = 125 - 91.03 - 81.94 - 34.44 = -82.41 \text{ dBm} \]

\[ = 0.574 \times 10^{-11} \text{ W} = 5.74 \times 10^{-12} \text{ W} \text{ or } 5.74 \mu\text{W} \]

e. From Eq. 2-92 of the Text

\[ S = \frac{P_t G_t}{4\pi R^2} \times 10^{-0.2} \leq 2 \text{ dB loss of the atmosphere} \]

\[ = \frac{10^2 \times 10^4}{4\pi (3.56 \times 10^3)^2} \times 10^{-0.2} \]

\[ = 6.28 \times 10^{-11} \times 10^{-0.2} = 3.96 \times 10^{-11} \text{ W/m}^2 \]
4. (30 points)

A vertical 0.4781λ (nominal half-wave) dipole is placed above ground as shown below

\[
\begin{array}{c}
\uparrow \\
\downarrow \\
0.15\lambda
\end{array}
\]

4 a. Draw the image antenna. Note that the phase of the image antenna for a vertical antenna is the same as that of the installed antenna.

Calculate the spacing \( d_z \) between the installed antenna and the image antenna.

6 b. Treating this as a \( z \)-element \( z \)-directed antenna array, write an expression for the radiated electric field and power density for this antenna above the ground plane in terms of \( r, \theta, \phi \).

6 c. Calculate the angle/s of maximum radiation.

7 d. Calculate the angle \( \theta \) for first null of radiation.

7 e. Calculate the gain of the antenna including the mutual impedance effects.
a. The single antenna is sketched here.
Center to center spacing $d_z$ between the installed and the single antenna = 0.8 $\lambda$.

b. From Eq. (10) on p. 24 of the class notes, the array factor for this 2-element ($N_z = 2$) $\pm$-directed antenna array can be written as

$$AF = \frac{e^{j\Psi/2}}{\sin \Psi/2} = \frac{2 e^{j\Psi/2} \cos(\Psi/2)}{\sin \Psi/2} \tag{1}$$

where $\Psi = \beta d_z \cos \Theta = 1.6 \pi \cos \Theta \tag{2}$

$$E_T = E_0 \cdot AF$$

where for a "half wave" dipole, from p. 5 of the class notes, Eq. 5-6

$$E_0 = \frac{1}{r} \cdot \frac{\int_{-\Pi}^{\Pi} F(\Theta) e^{-j \beta r}}{r} = \frac{1}{r} \cdot \frac{\int_{-\Pi}^{\Pi} F(\Theta) e^{-j \beta r}}{r}$$

$$= \frac{1}{r} \cdot \frac{\int_{-\Pi}^{\Pi} 2 \cdot \text{Prad} \cdot \text{Re} \cdot [1 \cdot \beta r]}{r} \tag{3}$$

From Eq. (11) on p. 6 of class notes

$$F(\Theta) = \frac{\cos(\Theta/2) \cos(\Phi)}{\sin \Theta} \tag{4}$$

Thus $E_T = \left[ \frac{1}{r} \cdot \frac{\int_{-\Pi}^{\Pi} 2 \cdot \text{Prad} \cdot \cos(\Theta/2) \cos(\Phi)}{\sin \Theta} \right] \cdot \left[ 2 e^{j(0.8 \pi \cos \Theta)} \right]$ $\cdot \left[ e^{-j \beta r} \right] \tag{5}$

It is clear that $E_T$ depends only on $\Theta$ and is independent of angle $\Phi$, which is due to circular symmetry of this antenna.
c. From Eq. (5) on the previous page, for angles $\theta$ of max. 16 radian

\[ 0.8 \pi \cos \theta = 0 \quad \text{i.e.} \quad \theta = 90^\circ \text{ which is} \]
in the horizontal plane.

d. For the angle $\theta$ for zero radiation from Eq. (5)

\[ 0.8 \pi \cos \theta \frac{FN}{FN} = 90^\circ = \frac{\pi}{2} \]

\[ \theta = \cos^{-1} \left( \frac{0.5}{0.8} \right) = 51.3^\circ \]

(Also the angle $\theta = 90^\circ$ i.e. along the orientation of the antenna (z-axis) due to the term $\frac{\cos (\pi/2 + \theta)}{\sin \theta}$.)

e. From p. 46 of class notes for this z-directed colinear array

\[ Z_1 = Z_{11} + Z_{12} \frac{I_2}{I_1} = Z_{11} + Z_{12} \]

\[ = (73 + j42) + (\frac{1}{2} - j5) \]

\[ = 71 + j37 \]

From Eq. 55-1 on p. 33 of class notes

\[ D_{Array} = N^2 D_0 \frac{R_{Ao}}{R_{Ai}} = (2)^2 \times 1.64 \times \frac{73}{71} \]

\[ = \boxed{6.744} \]
